Received December 21, 2023; accepted April 12, 2024.

Abstract The springing up of large language models (LLMs) has shifted the community from single-task-orientated natural language processing (NLP) research to a holistic end-to-end multi-task learning paradigm. Along this line of research endeavors in the area, LLM-based prompting methods have attracted much attention, partially due to the technological advantages brought by prompt engineering (PE) as well as the underlying NLP principles disclosed by various prompting methods. Traditional supervised learning usually requires training a model based on labeled data and then making predictions. In contrast, PE methods directly use the powerful capabilities of existing LLMs (e.g., GPT-3 and GPT-4) via composing appropriate prompts, especially under few-shot or zero-shot scenarios. Facing the abundance of studies related to the prompting and the ever-evolving nature of this field, this article aims to 1) illustrate a novel perspective to review existing PE methods within the well-established communication theory framework, 2) facilitate a better/deeper understanding of developing trends of existing PE methods used in three typical tasks, and 3) shed light on promising research directions for future PE methods.

Keywords prompting method, large language model, communication theory

### 1 Introduction

Large language models (LLMs) (e.g., GPT-3<sup>[\[1\]](#page-15-0)</sup>,  $GPT-4^{[2]}$  $GPT-4^{[2]}$  $GPT-4^{[2]}$ , LLaMa<sup>[\[3\]](#page-15-2)</sup>) make it possible for machines to understand users' attention accurately, thus revolutionizing the human-computer interaction (HCI) paradigm. Compared with traditional machine systems like databases and search engines, LLMs demonstrate impressive capability in understanding, generating, and processing natural language, facilitating a series of services ranging from personal assistants<sup>[\[4\]](#page-15-3)</sup>, healthcare<sup>[[5](#page-15-4)]</sup> to e-commercial tools<sup>[\[6\]](#page-15-5)</sup> via a unified natural language interface between users and machines.

The research paradigm around LLM has shifted from single-task-orientated natural language processing (NLP) research to a holistic end-to-end multitask learning approach. Along this line of research endeavors, LLM-based prompting engineering (PE) methods<sup>[[1](#page-15-0), [7\]](#page-15-6)</sup> have attracted much attention, partially because they are the key techniques in making full use of the superior capabilities of LLMs via constructing appropriate prompts. PE refers to the process of carefully constructing instructional prompts to steer and shape the behavior of LLMs, and it greatly helps in bridging the gap between the pre-training tasks used to construct the LLM with the down-streaming tasks queried by the end users. Through careful prompt designing, users can steer LLM's output in the desired direction, shaping its style, tone, and content to align with their goals.

To this end, numerous prompt engineering (PE) methods have been explored with the notable progress of LLM advancement and technologies<sup>[[7](#page-15-6)-[24\]](#page-16-0)</sup>. A common theme of PE development lies in continuously improving accuracy and responsiveness of designed prompts, which often include components like Role, Context, Input, Output Format, and Examples. Specifically, prompt template and answering engineer-

Survey

<sup>©</sup>Institute of Computing Technology, Chinese Academy of Sciences 2024

ing have evolved from solely utilizing discrete prompts to continuous prompts, and even to exploring hybrid prompts that combine continuous and discrete elements, which provides a larger optimization space to achieve better performance. With the emerging capabilities of LLMs, these models can leverage their in-context learning abilities to plan and utilize external tools, significantly enhancing their performance in specialized domains and broadening their applications across diverse fields.

Following these studies, representative PE methods can be categorized as three groups that correspond to three prompting tasks proposed to improve the qualities of LLMs' outputs, namely prompt template engineering, prompt answer engineering, and multi-prompt engineering and multi-turn prompt engineering, respectively. An example of the input and output for the above-mentioned tasks can be found in [Table 1](#page-2-0).

[*Z*] restaurant" to enforce the LLM to fill the desired comments in the blank (i.e.,  $[Z]$ ). Essentially this • First, prompt template engineering methods aim to carefully design a piece of "text" that guides the language models to produce the desired outputs. For example, in [Table 1,](#page-2-0) to finish a classical sentiment detection for an input *A*="Delicious dining options close to my current location", the prompt template engineering designs a template "[*A*] In summary, it was a type of template engineering method induces LLM to focus on word embeddings that are relevant to the questions. A common designing principle of existing prompt template engineering methods is to better align information between users and LLMs. Such a trend is manifested by the evolution from using discrete prompts (i.e., a piece of human-readable text)<sup>[\[9,](#page-15-7) [11\]](#page-15-8)</sup> to continuous ones (i.e., a continuous taskspecific vector) $[13, 20]$  $[13, 20]$  $[13, 20]$ .

• Second, prompt answer engineering  $[7]$  $[7]$  $[7]$  refers to the process of exploring the vast answer space and a map to the desired, intended output, which enhances users' understanding of the information encapsulated within the LLM. For the same example in [Table 1,](#page-2-0) the prompt answer engineering aims to find a mapping from the result "good" obtained from the LLM to the desired answer "positive". The field of prompt answer engineering is currently witnessing a notable development trend characterized by the pursuit of models that excel in decoding model information from simple mapping to complex mapping to enhance human comprehension.

• Third, multi -prompting methods mainly apply ensemble techniques<sup>[\[10](#page-15-10)]</sup> to mitigate the sensitivity of LLM to different formulations and to obtain a more stable output. In [Table 1,](#page-2-0) the multi-prompting methods combine three different templates (i.e., 1) "It was a  $[Z]$ " place, 2) "A  $[Z]$  place to eat", and 3) "In general, it was  $[Z]^n$ ), and their inference results (i.e., 1) "good", 2) "fantastic", and 3) "okay") to obtain the final desired one (i.e., "positive"). Later, as LLMs become more capable, multi-turn prompt methods attract more attention that aims to provide more context to LLM by leveragin[g](#page-16-2)i[nf](#page-16-3)ormation either from LLM itself or external tools $[25, 26]$  $[25, 26]$  $[25, 26]$ . In the field of multiprompting methods, researchers are endeavoring to develop adaptive strategies that enhance LLM's ability to task planning and the utilization of tools.

In this article, we summarize the prompting methods from a communication theory perspective with which the ultimate goal of PE is to reduce the information misunderstanding between [the user](#page-3-0)s and the LLMs. Therefore, as delineated in [Section 2](#page-3-0), the communication theory perspective provides a coherent explanation of different PE methods in terms of their objectives and underlying principles. Moreover, this novel perspective also offers and presents insights into scenarios where existing prompting methods come short.

T[he remain](#page-3-0)der of the article is structured as follows: [Section 2](#page-3-0) details the overview of the prompting [methods fr](#page-5-0)[om](#page-7-0) the [c](#page-9-0)ommunication theory perspective. [Sections 3,](#page-5-0) [4](#page-7-0), and [5](#page-9-0) review and summarize the recent

<span id="page-2-0"></span>

Stage	$_{\mathrm{Input}}$	Output
Prompt template engineering	Delicious dining options close to my current location	Delicious dining options close to my current location. In summary, it was a $[Z]$ restaurant
Large language model	Delicious dining options close to my current location. In summary, it was a $[Z]$ restaurant.	Delicious dining options close to my current location. In summary, it was a good restaurant
Prompt answering engineering	Good	Positive
Multi-prompt	1) It was a $[Z]$ place; 2) A $[Z]$ place to eat; 3) In general, it was $[Z]$	1) good, 2) fantastic, and 3) okay

progresses from three PE tasks namely prompt template engineering, prompt answer engineering, and multi-prompt engineering and multi-turn prompt engineering, respectively. [Sections 6](#page-13-0) discusses other related surveys and potential research directions. Finally, we conclude this article in [Section 7](#page-14-0) by summarizing significant findings and discussing potential research directions. We summarize the main symbols and abbreviations in [Table 2](#page-3-1) for the convenience of readers.

## <span id="page-3-0"></span>2 Communication Theory Perspective of Prompting Methods

The study of modern communication theory, which dates back to the 1940s and the following decades, gave rise to a variety of communication models including both linear transmission models and non-linear models such as interaction, transaction, and convergence models<sup>[[27](#page-16-4)–[29](#page-16-5)]</sup>. A common theme of these early studies is to analyze how individuals utilize verbal and non-verbal interactions to develop meaning in diverse circumstances. Conceptually, the communication process is often modeled as a chain of information processing steps involving encoding, transmitting, and decoding of messages, between a sender and a receiver.

To give a better illustration,  $Fig.1(a)$  $Fig.1(a)$  depicts the classical Model of Communication in the communication theory, which includes a sender encoding a message and transmitting it to the receiver over a channel. Then, the receiver decodes the message and delivers some type of response. During the transmission process, the message may be distorted due to noise, leading to the necessity of multi-turn interaction.

The original communication theory is widely uti-lized to examine factors including social<sup>[[30\]](#page-16-6)</sup>, cultural<sup>[[31\]](#page-16-7)</sup>, and psychological $[32]$  $[32]$  that influence human communication. The overall goal of communication theory is to reveal and clarify the common human experience of interacting with others through information exchange.

Among early studies of various communication models, we are particularly inspired by two influential works, namely, Shannon-Weaver Model of Communication[\[33](#page-16-9)] and Schramm Communication Model[\[34](#page-16-10)] . Shannon-Weaver's pioneering work, first pub-

Table 2. Summary of Key Symbols and Abbreviations

<span id="page-3-1"></span>

Symbol	Description
<b>PES</b>	Prompt engineering system, a mathematical formulation for interactive user-LLM communication
$\boldsymbol{X}$	Input to the LLM, which can be text or other data
$P_T$	Prompt template, a carefully crafted piece of text designed to guide the LLM to produce desired outputs
$P_A$	Prompt answer, the output yielded by the LLM following the input $P_T$
Y	Target output or desired result from the LLM
$g_{\omega_T}$	Function representing the mapping from the input X to $P_T$
$f_{\theta}$	Function representing the mapping from the prompt $P_T$ to the answer $P_A$
$h_{\omega_A}$	Function representing the mapping from the answer $P_A$ to Y
I(X;Y)	Mutual information between two random variables X and Y, used in the context of maximizing information flow in PES

<span id="page-3-2"></span>

Fig.1. Prompting methods from the communication theory perspective. (a) Classical interaction model of communication. (b) Different aspects of existing prompting methods.

lished in 1948, provides a strong mathematical foundation to analyze information flow between an active sender and a passive receiver. It is however over-simplistic in the sense that it does not take into account of complexities involved in interactive communication between active senders and receivers, who may respond by sending their messages as a form of feedback. The interaction models of communication were first studied by Scharmm and published in his 1954 book<sup>[[34\]](#page-16-10)</sup>, which pictorially illustrates the feedback loop as depicted in  $Fig.1(a)$  $Fig.1(a)$ . Nevertheless, Scharmm's model falls short of rigorous theoretical and mathematical formulation to accommodate quantitative analysis, e.g., information gain or mutual information between senders and receivers.

Various prompting engineering methods for LLM, in our view, can be understood from Scharmm's model point of view (see  $Fig.1(b)$  $Fig.1(b)$ ). In the same vein of Shannon-Weaver's analysis, we, therefore, delineate a mathematical formulation of prompting engineering systems for interactive user-LLM communication as follows.

Definition 1 (PES). *A prompt engineering system (PES) consists of a processing chain:*

$$
X \xrightarrow{g_{\omega_T}} P_T \xrightarrow{f_{\theta}} P_A \xrightarrow{h_{\omega_A}} Y,
$$

*where*  $g_{\omega_T}$  *represents the mapping from the input X to P*<sub>*T*</sub>, *f*<sup> $\theta$ </sup> *denotes the mapping from the Prompt*  $P_T$  *to the answer*  $P_A$ *, and*  $h_{\omega_A}$  *denotes the PA to the answer*  $P_A$  *to the output*  $Y$  (see *[Fig.1](#page-3-2)(b) for an illustration).*

*X mize the mutual information between the inputs and outputs*  $Y$ *, i.e.,* Definition 2 (Goal of PES). *PES aims to maxi-*

<span id="page-4-0"></span>
$$
\max_{\omega_T, \ \omega_A} I(X, Y) = \max_{\omega_T, \ \omega_A} I(X, h_{\omega_A} \circ f_{\theta} \circ g_{\omega_T}(X)), \quad (1)
$$

 $where f \circ g(x) = f(g(x)).$ 

It is worth noting that prompt engineering is consistently divided into two procedures: prompt template engineering and prompt answer engi[ne](#page-4-0)ering. Each procedure has specific goals similar to ([1\)](#page-4-0) that align with its intended purpose.

While the capacit[y](#page-16-11) in Definition 2 is well-known in i[nf](#page-4-0)ormation theory[[35\]](#page-16-11) , how [to re](#page-3-2)ach the maximum of  $(1)$  $(1)$  for LLMs illustrated in [Fig.1](#page-3-2)(b) remains an unexplored research direction. There exists a large variety of prompting engineering methods, which, in our view, essentially aim to reduce information misunderstanding between users and LLMs. In other words, they aim to reach the capacity of PES as defined. For instance, Sorensen *et al*. [[36\]](#page-16-12) demonstrated selecting the prompt with the greater mutual information (MI) enhanced the model performance. This underscores the objective of PE techniques, which is to optimize the mutual information between prompts and answers (see practical examples in Appendix C of  $[36]$  $[36]$ ). This connection between PES and the communication models has never been explicitly stated before.

 $(X \xrightarrow{g_{\omega_T}} P_T)$ , prompt answer engineering  $(P_A \xrightarrow{h_{\omega_A}} Y)$ , Moreover, the existing work can be divided into three categories: prompt template engineering and multi-prompt engineering and multi-turn prompt engineering as shown in  $Fig.1(b)$  $Fig.1(b)$ . Specifically, the prompt template engineering aims to reduce the encoding error or look for the prompt that is easily understood by the machine, while the prompt answering engineering aims to reduce the decoding error or look for the prompt that can be easily understood by the human. The development of LLMs aims to enhance the capability of the receiver that could better handle users' information needs, and most importantly, the multi-turn prompting and multi-prompt engineering aim to constantly reduce the information misunderstanding via multi-turn interactions.

<span id="page-4-1"></span>• Prompt template engineering aims to optimize

$$
\max_{\omega_T} I(X, P_A) = \max_{\omega_T} I(X, f_\theta \circ g_{\omega_T}(X)), \qquad (2)
$$

which looks for an additional piece of text, namely a prompt, to steer the LLMs to produce the desired outputs for downstream tasks. From the communication theory perspective, it acts as an "encoder" to bridge the gap between the users and the LLMs by encoding the messages in a way that the model can understand [and then](#page-5-0) elicit knowledge from LLMs (see details in [Section 3](#page-5-0)). In the encoding process, the challenge lies in the accurate understanding of the user's intention by LLM with limited instruction following capability. Template engineering aims to reduce this mismatch by translating the user's request to a format that could be better understood by LLM.

<span id="page-4-2"></span>• Prompt answer engineering aims to optimize

$$
\max_{\omega_A} I(P_T, Y) = \max_{\omega_A} I(P_T, h_{\omega_A} \circ f_{\theta}(P_T)), \qquad (3)
$$

a prompt answer  $P_A$  and 2) to look for a map to the target output  $Y$  that will result in an accurate predicwhich focuses on developing appropriate inputs for prompting methods. It has two goals: 1) to search for tive model. In the decoding process, LLM-generated output often carries redundant information in addi-

mate outputs (i.e., Y) are well aligned with that of tion to the expected answer due to its unlimited output space. Answer engineering aims to confine the output space and extract the target answer. The field of prompt answer engineering is currently witnessing a notable development trend characterized by the pursuit of effective answer engineering such that ultiend users' expectations (see details in [Section 4](#page-7-0)).

• To further reduce the information misunderstanding, the [u](#page-4-1)ser cou[ld](#page-4-2) conduct multi-interaction accordingto  $(2)$  $(2)$  and  $(3)$ , called multi-prompt/multiturn PE. Multi-prompting methods aim to optimize

$$
\max_{\omega_{T_1},\dots,\omega_{T_M}} \sum_{i=1}^M I(X, f_\theta \circ g_{\omega_{T_i}}(X)),
$$

which mainly applies ensemble techniques<sup>[[10\]](#page-15-10)</sup> to mitigate the sensitivity of LLM to different formulations and to obtain a more stable output. Later, as LLMs become more capable, multi-turn prompt methods focus on providing more context to LLM by leveraging multiple commun[ica](#page-16-2)[tio](#page-16-3)n procedures between the ma-chine and person<sup>[[25,](#page-16-2) [26](#page-16-3)]</sup>. In the field of multi-prompting methods, researchers are endeavoring to develop adaptive strategies that enhance LLM's ability to task planning and the utilization of tools. The adaptive and iterative nature of multi-pr[ompting m](#page-9-0)ethods is by the communication theory (see [Section 5](#page-9-0) for an elaborated explanation).

#### <span id="page-5-0"></span>3 Prompt Template Engineering

Given the information chain  $X \to P_T \to P_A$ , the answer  $P_A$  is determined by the prompt-processed  $P_T$ and model M with pre-trained weights  $\theta$ . Suppose that  $\bar{P}_A$  is the targeted prediction, the key problem of that maximizes the probability  $p(\bar{P}_A|M, P_T, \theta)$  on dilated into three categories: constructing  $P_T$ , ranking  $P_T$ , and tuning  $P_T$ . prompt template engineering is to find a good prompt verse downstream tasks with limited data. To obtain the optimal prompt, current work $[8-24]$  $[8-24]$  $[8-24]$  $[8-24]$  can be formu-

#### 3.1 Constructing the Prompt

The basic motivation of constructing  $P_T$  is to transform the specific task to make it align with the pre-training objective (i.e., next-word prediction, masked LM) of the LM. Existing prompt construc-tion methods<sup>[[8](#page-15-11)–[11,](#page-15-8) [15,](#page-15-12) [37](#page-16-13)–[39\]](#page-16-14)</sup> could be categorized into five different approaches as shown in [Table 3](#page-5-1), which are discussed in detail as follows.

### 3.1.1 Manually-Designed

Initially, the prompt templates are manually designed in the natural language based on the user's experience, and they have been validated to be able to improve the performances of downstream tasks, espe-cially in a zero-shot setting<sup>[\[1,](#page-15-0) [8](#page-15-11)]</sup>. The most frequent style is to reformulate the original task as a "fill-in-the-blank" cloze one<sup>[\[9,](#page-15-7) [10\]](#page-15-10)</sup>, and the answer is obtained by predicting the words in the given "[mask]" place. For example, as illustrated in [Table 3](#page-5-1), Petroni *et al.*[[9](#page-15-7)] manually designed prompts to re-structure the relational knowledge, while studies like [\[10](#page-15-10), [37](#page-16-13)] focused on solving the text classification and language understanding tasks by several self-defining prompt patterns and proposed $[10]$  $[10]$  a new training procedure named PET. Another line of work involves developing prefix prompts for generation tasks, which provide instructions and steer the LLMs to finish the sentence. For example, a summarization task can be handled by adding "TL;DR:" $[8]$ , and a translation task can be conducted into "English Translate to Spanish:"<sup>[\[38](#page-16-15)]</sup>. Even though manually designed prompts show some effectiveness<sup>[\[39](#page-16-14)]</sup>, they are also criticized for being time-consuming and unstable<sup>[[15\]](#page-15-12)</sup>. A subtle difference in the designed prompts may result in a substantial performance decrease. As such, how to explore the prompt space and construct prompts more thoroughly and more effectively becomes an important and challenging issue.

#### 3.1.2 Heuristic-Based

The heuristic-based methods focus on finding

Table 3. Summary of Prompt Construction Methods

<span id="page-5-1"></span>

Method	Automated	Gradient-Free	Few-Shot	Zero-Shot	Stability	Interpret-Ability
$\text{Manually-designed}^{[8-10]}$						
Heuristic-based $[11, 19, 40]$						
Paraphrasing-based <sup>[11, 14, 41]</sup>						
Generation-based $[17, 42]$						
Optimization-based $[12, 22]$						

prompts by some intuitive strategies. For example, to construct more flexible and diverse prompts for different examples (rather than fixed ones), Jiang *et al.*<sup>[[11\]](#page-15-8)</sup> proposed to use the most frequent middle words and the phrase spanning in the shortest dependency path that appeared in the training data as a prompt. This method shows a large performance gain compared with the manually-designed prompts. Han *et al.*<sup>[[19\]](#page-16-16)</sup> tried to form task-specific prompts by combining simple human-picked sub-prompts according to some logic rules. Different from the above methods, Logan *et al.*[[40\]](#page-16-17) used an extremely simple uniform rule by null prompts, which only concatenates the inputs and the "[mask]" token, and it is able to gain a comparable accuracy with manually-defined prompts.

#### 3.1.3 Paraphrasing-Based

The paraphrasing-based methods are widely used in data augmentation, aiming at generating augmented data that is semantically related to the original text, and this could be achieved in various ways using machine translation, model-based generation, and rule-based generation<sup>[\[43](#page-16-21)]</sup>. The paraphrasing-based methods could naturally be used to construct prompt candidates based on the original text, and we could further select the best one or integrate them to provide better performance. Representative studies in-cludes $[11, 14, 41]$  $[11, 14, 41]$  $[11, 14, 41]$  $[11, 14, 41]$  $[11, 14, 41]$  $[11, 14, 41]$ . Specifically, Jiang *et al.*<sup>[[11\]](#page-15-8)</sup> used back-translation to enhance the lexical diversity while keeping the semantic meaning. Yuan *et al.*[[41\]](#page-16-18) manually created some seeds and found their synonyms to narrow down the search space. Haviv *et al.*[[14\]](#page-15-13) used a BERT-based model to act as a rewriter to obtain prompts that LLMs can understand better.

#### 3.1.4 Generation-Based

The generation-based methods treat prompt searching as a generative task that can be carried out by some LMs. For example, Gao *et al.*<sup>[[17\]](#page-15-14)</sup> first leveraged the generative ability of  $T5^{[38]}$  $T5^{[38]}$  $T5^{[38]}$  to fill in the placeholders as prompts, and then the prompts could be furthe[r i](#page-16-19)mproved by encoding domain-specific in-formation<sup>[\[42](#page-16-19)]</sup>.

#### 3.1.5 Optimization-Based

To alleviate the weakness of insufficient exploration space faced by existing methods, the optimized-based methods try to generate prompts guided by some optimization signals. For example, Shin *et al.*[\[12](#page-15-15)] employed gradients as the signals, and then searched for discrete trigger words as prompts to enrich the candidate space. Deng *et al.*[\[22](#page-16-20)] generated the prompt using a reinforced-learning approach that is directed with the reward function.

### 3.2 Ranking the Prompt

After obtaining multiple prompt candidates with the above-mentioned methods, the next step is to rank them to select the most effective one. Existing studies solve this problem by finding prompts that are close to the training samples to reduce the information mismatch between the pre-training and inference phases.

## 3.2.1 Execution Accuracy

Since the prompts are designed to accomplish specific downstream tasks, it is intuitive and straightforward to evaluate their performance by measuring the execution accuracy on those tasks<sup>[[11,](#page-15-8) [17,](#page-15-14) [44](#page-16-22)]</sup>.

#### 3.2.2 Log Probability

The log probability criterion prefers the prompt that delivers the correct output with higher probability, rather than being forced to give the exact answer. For example, a prompt template that can work well for all training examples is given the maximum generated probability in [[17\]](#page-15-14). Furthermore, language models can also be utilized to evaluate the quality of prompts. In [[45\]](#page-17-0), the prompt with the highest probability given by an LM is selected, which indicates closer to the general expression that appears in the training dataset.

## 3.2.3 Others

the top- $k$  prompt. For example, Shin *et al.*<sup>[\[12](#page-15-15)]</sup> regard-Other criteria can be used to select the top one or ed the words that are estimated to have the largest performance improvement as the most crucial elements.

### 3.3 Tuning the Prompt

Recent studies turn to optimizing the prompt as continuous embeddings to further improve the performance. The main idea is to learn a few continuous parameters, referred to as soft prompts, and these continuous parameters can be optionally initialized by the previously obtained discrete prompt. Li *et al.*[[13\]](#page-15-9) first introduced a continuous task-specific "prefix-tuning" for generative tasks. Studies like [\[20](#page-16-1)] and[[15\]](#page-15-12) adopted a similar strategy and proved its effectiveness in various natural language understanding tasks. Following the above-mentioned studies, many improvements have been conducted to find better prompts, such as better optimizing strategies<sup>[\[16](#page-15-16)]</sup>, bet- $\text{ter}$  vector initialization<sup>[[21,](#page-16-23) [23](#page-16-24)]</sup>, and indicative anchors<sup>[\[15](#page-15-12)]</sup>. Furthermore, studies like  $[13, 20, 46]$  $[13, 20, 46]$  $[13, 20, 46]$  $[13, 20, 46]$  $[13, 20, 46]$  further point out that prompt position, length, and initialization all affect the performance of continuous prompts<sup>[\[13](#page-15-9), [20,](#page-16-1) [46\]](#page-17-1)</sup> ([Table 4](#page-7-1)). In this subsection, we summarize these factors as follows:

inserted into, that is, the prefix  $[PREFIX; X_T; Y],$  $\text{the } \text{~~infix~~} [X_T; INFIX; Y], \text{~~and~~} \text{~~the } \text{~~hybrid~~} \text{~~one}$  $[PREFIX; X_T; INFIX; Y]$ . There is no significant • *Different Positions*. There are three different positions for autoregressive LM that the prompt can be performance difference between those positions. Li *et al.*[[13\]](#page-15-9) showed that prefix prompt sightly outperforms infix prompt, and the hybrid one is much more flexible than the others.

• *Different Lengths*. There is no optimal length for all tasks, but there is always a threshold. The performance will increase before reaching the threshold, then it will either plateau or slightly decrease.

• *Different Initializations*. A proper initialization is essential for the performance of the prompts and the performance of random initialization is usually unsatisfactory. Typical methods include initialized by sampling real words<sup>[\[13](#page-15-9), [20](#page-16-1)]</sup>, using class labels<sup>[\[20](#page-16-1)]</sup>, using discrete prompts<sup>[[16\]](#page-15-16)</sup>, and using pre-trained based vectors[[21,](#page-16-23) [23](#page-16-24)] . Furthermore, the manually designed prompts serve as a good starting point for the following search process.

 $Fit^{[47]},$  $Fit^{[47]},$  $Fit^{[47]},$  Partial-k tuning, MLP-k tuning, side-Besides the above-mentioned methods, PE methods have also been used for tuning and constructing the LLMs. Typical methods in this area include Bittuning<sup>[[48\]](#page-17-3)</sup>, adapter tuning<sup>[\[49](#page-17-4)]</sup>, Ladder Side-Tuning<sup>[[50\]](#page-17-5)</sup>, and the essential Prompt Tuning $[13]$  $[13]$ . These methods aim to achieve a comparable performance by fine-tuning the whole network by only tuning some parts of the parameters of LLMs.

## 3.4 Trends for Prompt Template Engineering

There are two trends in prompt template engineering.

• Increased reliance on automated methods over manual design when constructing prompts, reducing the need for human involvement.

• Development of optimization -based techniques. The gradient-based searching method shows better performance than the derivative-free one in hard prompts construction while the soft prompts appear more promising than hard prompts.

From the communication theory perspective, the development history of prompting template engineering reflects the trends of utilizing prompts with stronger expressive ability to better capture the user's intent.

#### <span id="page-7-0"></span>4 Prompt Answering Engineering

As depicted in  $Fig.1(b)$  $Fig.1(b)$ , prompt answer engineering (PAE) aims to align LLMs outputs with the intended purpose. The use of PAE is motivated by the need to mitigate the gap between the capabilities of pre-trained LLMs and a large variety of requirements of different downstream tasks (see more discussion in [Section 2\)](#page-3-0). Technology-wise, PAE involves a set of methods that control the admissible answer space and optimization mechanisms of LLMs' output (see overview in [Table 5](#page-8-0)).

#### 4.1 Search for an Answer Space

#### 4.1.1 Pre-Defined Answer Space

This involves a set of pre-defined answers for the

Table 4. Summary of Prompt Tuning Methods

<span id="page-7-1"></span>

Work	Position	${\rm Length}$	Initialization
Prefix tuning $[13]$	Prefix, infix	200 (summarization), 10 (table-to-text)	Random, real words
Prompt tuning $[20]$	Prefix	1, 5, 20, 100, 150	Random, sampled vocabulary, class label
$P$ -tuning <sup>[15]</sup>	Hybrid	$3$ (prefix), $3$ (infix)	LSTM-trained
$\text{DART}^{[18]}$	Infix	3	Unused token in vocabulary
OPTIPROMPT <sup>[16]</sup>	Infix	5, 10	Manual prompt
$Dynamic^{[46]}$	Hybrid, dynamic	Dynamic	Sampled vocabulary

Answer Space Type	Answer Mapping Method	Work	Task Type
Optimizing the mapping	Discrete answer space	[10, 12, 17, 51]	Classification $\&$ regression
	Continuous answer space	52	Classification
Broadening the output	Discrete answer space	11	Generation
Decomposing the output	Discrete answer space	53	Classification
Manually mapping	Pre-defined answer	$\left  9, 54, 55 \right $	Generation

Table 5. Summary for Prompt Answer Engineering Methods

fined space. As an illustration, the answer space  $P_A$ question-answering task, e.g., pre-defined emotions ("happiness", "surprise", "shame", "anger", etc.) for the sentiment classification task. The model can then be trained to select the best answer from this pre-de-can be defined as the set of all tokens<sup>[[9](#page-15-7)]</sup>, fixed-length spans<sup>[[56\]](#page-17-6)</sup>, or token sequences<sup>[\[8\]](#page-15-11)</sup>. Furthermore, in certain tasks like text classification, question answering, or entity recognition, answers are crafted manually as word lists that pertain to relevant topics<sup>[[7](#page-15-6), [54,](#page-17-7) [55\]](#page-17-8)</sup>.

## 4.1.2 Discrete Answer Space

The discrete answer space refers to a set of specific and distinct answer options that a language model can choose from when generating a response to a given prompt.

Specifically, the possible answers are limited to a fixed set of choices, such as a small number of named entities or keyphrases (e.g., the total choice of the planet in the solar system is eight). The model can then be trained to identify whether the correct answer is among this set of possibilities  $[10-12]$  $[10-12]$  $[10-12]$ .

#### <span id="page-8-1"></span>4.1.3 Continuous Answer Space

The continuous answer space refers to a scenario where the possible answers or responses are not restricted to a predefined set of discrete options. Instead, the answers can take on a range of continuous values or be any text, number, or value within a broader, unbounded spectrum<sup>[\[52](#page-17-9), [57](#page-17-10)]</sup>.

The model can then be trained to predict a point in the continuous space that corresponds to the correct answer.

### 4.1.4 Hybrid Approach

This involves combining multiple methods to design the answer space, such as using a pre-defined list of entities for certain types of questions, but allowing for free-form text answers for other types of questions<sup>[\[58](#page-17-11)]</sup>.

Remark 1. *Answer shapes summarized as follows are also needed in prompt answer engineering. In practice, the choice of the answer shape depends on the desired outcome of the task.*

• *Tokens: individual tokens within the vocabulary of a pre-trained language model, or a subset of the vocabulary.*

• *Span: short sequences of multiple tokens, often comprising a phrase or segment of text.*

• *Sentence: a longer segment of text that can encompass one or more complete sentences.*

## 4.2 Search for an Answer Mapping

There are several strategies to search for an answer mapping.

## 4.2.1 Manually Mapping

swers space  $P_A$  to output Y is obvious such that this In many cases, the mapping from potential anmapping can be done manually. For instance, the answer is output itself for the translation  $task^{[9]}$  $task^{[9]}$  $task^{[9]}$  such that the mapping is identity mapping. Additionally, Yin *et al.*<sup>[\[54](#page-17-7)]</sup> designed related topics ("health", "food", "finance", "sports", etc.), situations ("shelter", "water", "medical assistance", etc.), or other possible labels. Cui *et al*. [\[55](#page-17-8)] manually proposed some entity tags, e.g., "organization", "person", and "location", for the named entity recognition problem.

## 4.2.2 Broadening Answer *P<sup>A</sup>*

Broadening  $P_A$  ( $P'_A = B(P_A)$ ) is expanding the anspace  $P_A$  by transferring the original prompt into othswer space to obtain a more accurate mapping. Jiang *et al*. [[11\]](#page-15-8) proposed a method to paraphrase the answer er similar expressions. In their approach, they employed a back-translation technique by first translating prompts into another language and then translating them back, resulting in a set of diverse paraphrased answers. The probability of the final output *can be expressed as*  $P(Y|x) = \sum_{y \in B(P_A)} P(y|x)$ , where  $B(Y)$  represents the set of possible paraphrased answers.

### 4.2.3 Decomposing the Output

Decomposing  $Y(D(Y))$  aims to expand the information of  $Y$ , which makes it easier to look for a map*gθ* ping . For example, Chen *et al.*[[53\]](#page-17-13) decomposed the be written as  $P(y|x) = \sum_{y \in D(Y)} P(y|x)$ . labels into several words and regarded them as the answer. Concretely, they decomposed label/output "per:city of death" into three separated words {person, city, death}. The probability of final output can

#### 4.2.4 Optimizing the Mapping

the pruned space  $\tilde{P}_A$  and search for a set of answers balizer  $v$ , is designed to identify sets of answers. Their approach involves estimating a verbalizer  $v$  by maxitioned on the verbalizer  $v$ . Shin  $et$   $al$ <sup>[[12\]](#page-15-15)</sup> proposed an *et al.*<sup>[\[17](#page-15-14)]</sup> constructed a pruned set  $\tilde{P}_A^c$  containing the likelihood for each class  $c$ . As for the second ap-There exist two approaches to optimizing the mapping function. The first approach is to generate within this pruned space. Schick *et al.*<sup>[[10,](#page-15-10) [51](#page-17-12)]</sup> introduced a technique for generating a mapping from each label to a singular token that represents its semantic meaning. This mapping, referred to as a vermizing the likelihood w.r.t. the traini[ng](#page-15-15) data condialternative approach for selecting the answer tokens. They employed logistic classifiers to identify the top-*k* tokens that yield the highest probability score, which toget[he](#page-15-14)r form the selected answer. In addition, Gao top-*k* vocabulary words based on their conditional proach, it investigates the potential of utilizing soft answer tokens that can be optimized through gradient descent. Hambardzumyan *et al.*[\[52](#page-17-9)] allocated a virtual token to represent each class label and optimized the token embedding for each class along with the prompt token embedding using gradient descent.

### 4.3 Trends for Prompt Answer Engineering

There are two trends in prompt answer engineering:

• Developing more robust and generalizable question-answering models that can handle more complex tasks and a broader range of inputs. For example, the answer space is some discrete spans at the beginning (see [Section 6\)](#page-13-0) and developed to the complex continuous space (see [Subsection 4.1.3\)](#page-8-1).

• There is also a focus on improving the quality and relevance of prompts to improve model performance. Specifically, several techniques have been explored, such as paraphrasing and pruning, after the direct mapping approach. More recently, optimiza-tion methods<sup>[\[59](#page-17-14), [60\]](#page-17-15)</sup> using gradient descent have been proposed to enhance accuracy.

The prompt answering engineering also shows a trend of exploring prompts to decode the machine language with less information loss, i.e., has a better understanding of the machine.

#### <span id="page-9-0"></span>5 Multiple Prompting Methods

Multiple prompts can be utilized to further reduce the information mismatch during the encoding and decoding process. These methods can be categorized into two main types, namely "multi-prompt engineering" and "multi-turn prompt engineering", depending on the interrelationship of prompts (see [Fig.2\)](#page-9-1). Multi-prompt engineering is akin to an ensemble system, whereby each response serves as a valid answer, and responses from multiple prompts are aggregated to produce a more stable outcome. This type

<span id="page-9-1"></span>

Fig.2. Overview of multiple prompting methods. (a) Multi-prompt methods utilize several similar prompts to produce a more stable result. (b) Multi-turn prompt methods produce the final result by aggregating responses from a sequence of prompts.

of method can be thought to extend the use of prompts in the spatial domain. On the other hand, multi-turn PE entails a sequence of prompts, whereby subsequent prompts depend on the response generated from previous prompts or the obtaining of the final answer relies on multiple responses. Consequently, this type of method can be viewed as an extension in the temporal domain. [Table 6](#page-10-0) summarizes the main multiple prompting methods.

## 5.1 Multi-Prompt Engineering Methods

Multi-prompt methods employ multiple prompts with similar patterns during the inference aiming to enhance information preservation. This meth[od](#page-19-0) [i](#page-19-1)s closely associated with assembling techniques<sup>[\[91](#page-19-0)–[93\]](#page-19-1)</sup>. Although the primary motivation is to exploit the complementary advantages of different prompts and reduce the expenses associated with PE, it can also be integrated with prompt-engineering techniques to further improve efficacy. From a communication theory perspective, multi-prompt engineering can be considered as sending multiple copies of the message to ensure the authentic delivery of data (see Fig.  $3(a)$ ).

#### 5.1.1 Expanding the Prompt

Expanding the prompt  $P_T$  aims to cover a larger put,  $X_A$ , can be obtained by aggregating the responssemantic space around the sender's true intention, and a more stable approximation of the target outes.

Jiang *et al.*<sup>[[11\]](#page-15-8)</sup>, Lester *et al.*<sup>[\[20](#page-16-1)]</sup>, and Hambardzumyan *et al.*[[52\]](#page-17-9) proposed to combine outputs of different prompts to g[et](#page-17-16) the final result for classification tasks. Qin *et al.*[\[61](#page-17-16)] incorporated multi-prompt ideas with soft prompts and optimized the weights of each [pr](#page-16-18)ompt together with prompt parameters. Yuan *et al.*[[41\]](#page-16-18) proposed to use text generation probability as the score for text generation evaluation, and aggregated multiple results of different prompts as the final score.

Table 6. Summary of PE Methods Involving Multiple Prompts

<span id="page-10-0"></span>

	Method	Language Understanding	Language Generation	Reasoning
Multi-prompt	Expanding $P_T$	[11, 20, 52, 61]	41	$\hspace{0.1mm}-\hspace{0.1mm}$
	Diversifying $P_A$			$62 - 67$
	Optimizing $\theta$	[10, 37]	[17, 68]	$\hspace{0.1mm}-\hspace{0.1mm}$
Multi-turn prompt	Decomposing $P_T$		[59, 60, 69]	$ 70 - 77 $
	Refining $P_T$	$\overline{\phantom{a}}$	[78, 79]	$[25, 60, 79-82]$
	Augmenting $P_T$	$\overline{\phantom{a}}$	[83, 84]	$85 - 87$
	Optimizing $\theta$		[59, 69]	$ 87 - 90 $

<span id="page-10-1"></span>

Fig.3. Schematic illustrations of multi-prompting methods. (a) Multi-prompt methods utilize several similar prompts to produce a more stable result. (b) Multi-turn prompt methods mainly leverage LLMs or external tools to provide clearer and more helpful context.

### 5.1.2 Diversifying the Answer

Different from expanding the prompt  $P_T$  whose main goal is to leverage the input space around  $P_T$ , diversifying the answer  $P_A$  aims to exploit the various "thinking paths" of the LLM through sampling its decoder. This is especially effective for handling complex tasks, such as mathematical and reasoning problems.

Wang *et al.*[\[62](#page-17-17)] proposed a self-consistency method based on the Chain-of-Thoughts (CoT) which samples multiple reasoning paths and selects the most consistent answer by majority voting or weighted averaging. Lewkowycz *et al*. [[63](#page-17-18)] applied a similar idea to quantitative problems by combining multiple prompts and output sampling. Wang *et al.*<sup>[\[64](#page-17-19)]</sup> investigated various ensemble variants in reasoning problems and found that rational sampling in the output space is more efficient. These methods solely use the final answer as the selection criterion and do not exploit the generated rationals from various sampling paths. To take advantage of these intermediate results, Li *et al.*[[65\]](#page-18-11) proposed to generate more diversified reasoning paths with multiple prompts and used a model-based verifier to select and rank these reasoning paths. Fu *et al.*[\[66](#page-18-12)] introduced a complexity-based metric to evaluate reasoning paths and prioritize those with higher complexity in the aggregation. Weng  $et \ al.<sup>[94]</sup>$  $et \ al.<sup>[94]</sup>$  $et \ al.<sup>[94]</sup>$  employed the LLM to self-verify various reasonings by comparing predicted conditions using the generated reasonings to original conditions. The consistency score is then used to select the final result. Yao *et al.*[[95\]](#page-19-5) proposed the "Tree of Thoughts" to explore the intermediate steps across various reasoning paths, and used the LLM to evaluate the quality of each possible path. Besta *et al.*[\[67](#page-18-0)] further proposed the "Graph of Thoughts" to treat the various reasoning paths as graphs so that the essence of the thought networks can be extracted.

#### 5.1.3 Optimizing the Model

This line of work treats multiple prompts as a label generator to address the sample deficiency problem. Schick *et al.*<sup>[[10\]](#page-15-10)</sup> first proposed pattern-exploiting training (PET) that employs a knowledge distillation strategy to aggregate results from multiple promptverbalizer combinations (PVP). They first utilized PVP pairs to train separate models that generate pseudo-labels for unlabeled datasets. This extended dataset was then used to train the final classification model. Schick *et al.*[\[96](#page-19-6)] extended this idea to the text generation task by using the generation probability of decoded text as the score. Gao *et al.*[\[17](#page-15-14)] used a similar method for automatic template generation. Schick *et al.*[\[37](#page-16-13)] further expanded PET with multiple verbalizers. This was achieved by introducing sample-dependent output space.

## 5.2 Multi-Turn Prompt Engineering Methods

two components: 1) decomposing the prompt  $P<sub>T</sub>$  into and 2) modifying the prompt  $P<sub>T</sub>$  to generate better *X* nents can [help to](#page-10-1) bridge the gap between complex and  $Y$  (see [Fig.3](#page-10-1)(b)). Multi-turn prompt engineering methods involve decomposing the full prompting task into several subtasks, each addressed by a corresponding prompt. This process typically entails a sequence of encoding and decoding operations, where subsequent prompts may depend on the decoded message from previous prompts or each prompt is responsible for a sub-task. The outcome can be obtained either from the result of the last prompt or by aggregating the responses generated by all prompts. This strategy is designed to tackle challenging tasks, such as complex mathematical questions or reasoning tasks. It mainly involves sub-tasks to reduce the difficulty of each sub-task; intermediate results for later steps. These two compo-

### 5.2.1 Decomposing the Prompt

Decomposing the prompt  $P_T$  is the first step in handling complex tasks, and a proper decomposition requires a good understanding of both [th](#page-19-7)e target task and the user's intention. Yang *et al.*[[97\]](#page-19-7) decomposed SQL operations using fine-tuned few-shot models and untrained zero-shot models combined with predefined rules. However, ruled-based decomposition heavily relies on human experiences, and thus it is desi[ra](#page-17-14)ble to automate this step with LLMs. Min *et al.*[\[59](#page-17-14)] proposed an unsupervised method that utilizes a similarity-based pseudo-decomposition set as a target to train a seq2seq model as a question generator. The decomposed simple question is then answered [b](#page-18-2)y an off-theshelf single-hop QA model. Perez *et al.*[\[69](#page-18-2)] treated the decomposition in a multi-hop reading comprehension (RC) task as a span prediction problem which only needs a few hundreds of samples. For each task, various decomposition paths are generated, with each sub-question answered by a single-hop RC model. Finally, a scorer model is used to select the top-scoring answer based on the solving path. Khot *et al.*[[60\]](#page-17-15) proposed a text modular network leveraging existing models to build a next-question generator. The training samples are obtained from sub-task models conditioned on distant supervision hints.

With the emergent general ability of LLMs, instead of training a task-specific decomposition model, LLMs are used to fulfill decomposition tasks. Zhou *et al.*[[70\]](#page-18-3) proposed the least-to-most prompting method where hard tasks are first reduced to less difficult subtasks by LLMs. Then answers from previous subproblems are combined with the original task to facilitate subsequent question solving. Dua *et al.*[[71\]](#page-18-13) employed a similar idea and appended both questions and answers from the previous stage to the subsequent prompt. Creswell *et al.*<sup>[\[72](#page-18-14)]</sup> proposed a selectioninference framework. It uses LLM to alternatively execute selecting relevant information from a given context and inferring new facts based on the selected information. Arora *et al.*[[73\]](#page-18-15) proposed to format the intermediate steps as open-ended question-answering tasks using LLMs. It further generates a set of prompt chains and uses wea[k](#page-18-16) supervision to aggregate the results. Khot *et al.*[\[74](#page-18-16)] proposed a modular approach for task decomposition with LLMs by usi[ng](#page-19-8) specialized decomposition prompts. Drozdov *et al.*[[98\]](#page-19-8) introduced a dynamic least-to-most prompting method for semantic parsing tasks by utilizing multiple prompts to build [a](#page-18-17) more flexible tree-based decomposition. Ye *et al.*[\[75](#page-18-17)] used LLMs as the decomposer for table-based reasoning tasks. LLMs are used for both sub-ta[ble](#page-19-9) extraction and question decomposition. Press *et al.*[\[99](#page-19-9)] proposed Self-Ask which decomposes the original task by repeatedly asking [the](#page-18-18) LLM if follow-up questions are needed. Wu *et al.*[\[76](#page-18-18)] proposed to build an interactive chaining framework with several primitive operations of LLMs to provide better transpa[ren](#page-18-4)cy and controllability of using LLMs. Wang *et al.*[[77\]](#page-18-4) proposed a Plan-and-Solve (PS) method that explicitly prompts LLM to devise a plan before solving the problem to address the missing-steps error in the reasoning.

## 5.2.2 Refining the Prompt

Refining the prompt  $P_T$  aims to construct a better representation of  $P_T$  based on the feedback from previous prompting results. This is especially important for multi-step reasoning, where the quality of generated intermediate reasonings has a critical impact on the final answer.

Following the success of the few-shot chain-ofthoughts (CoT) prompting method, Kojima *et al.*[\[25](#page-16-2)] proposed a zero-shot CoT method that utilizes the fixed prompt "Let's think step by step" to generate reasonings. These intermediate results are then fused with the original question to get the final answer. To select more effective exemplars, various methods were proposed. Li *et al.*[\[78](#page-18-5)] used LLMs to first generate a pseudo-QA pool, then a clustering method combined with similarity to the question was adopted to dynamically select QA pairs from the generated QA pool as demonstration exemplars. Shum *et al.*[[80\]](#page-18-19) leveraged a high-quality exemplar pool to obtain an exemplar distribution using a variance-reduced policy gradient estimator. Ye *et al.*<sup>[\[79](#page-18-6)]</sup> employed a self-consisten-cy method<sup>[[62\]](#page-17-17)</sup> to generate pseudo-labels of an unlabeled dataset. The accuracy of these silver labels serves as the selection criterion of exemplars. To further reduce the search complexity of various combinations, additional surrogate metrics were introduced to estimate the accuracy. Diao *et al.*<sup>[[81\]](#page-18-20)</sup> addressed this problem by using hard questions with human annotations as exemplars. The hardness is measured by the disagreement of results obtai[ned](#page-18-7) by multiple sampling of the LLM. Zhang *et al.*[[82\]](#page-18-7) proposed automatic CoT methods. They introduced question clustering and demonstration sampling steps to automatically select the best demonstrations for the CoT template.

#### 5.2.3 Augmenting the Prompt

Different from refining the prompt  $P_T$  which ter intermediate results, augmenting the prompt  $P_T$ mainly focuses on finding prompts that generate betleverages the exploitation of external information, knowledge, tools, etc. in the prompting. We present some examples in this field below, and for more [de](#page-19-10)tails we re[fer](#page-18-8) the reader to the specific survey  $[100]$ . Yang *et al.*<sup>[[83\]](#page-18-8)</sup> proposed a recursive reprompting and revision (3R) framework for long story generation leveraging pre-defined outlines. In each step, the context of the current status and the outline of the story are provided to the pr[om](#page-18-9)pt to ensure better content coherence. Yang *et al.*<sup>[[84\]](#page-18-9)</sup> proposed to use more detailed outlines so that the story generation LLM can focus more on linguistic aspects. Information retrieved from other sources is also often used to augment  $P_T$ . Yao *et al.*<sup>[\[101\]](#page-19-11)</sup> gave the LLM access to information from Wikipedia. Thoppilan *et al.*[[102](#page-19-12)] taught the LLM to use search engines for knowledge retrieval. More broadly, Paranjape *et al.*[\[26](#page-16-3)] introduced a task library to enable the LLM using external tools. Schick *et al.*<sup>[\[85](#page-18-10)]</sup> trained the LLM to use various external tools via API. Shen *et al.*[\[86](#page-18-21)] utilized an LLM as a central controller to coordinate other models to solve tasks.

## 5.2.4 Optimizing the Model

General LMs (language models) are not optimized for producing intermediate rationals or decomposing a complex task or question. Before the era of LLMs, these tasks require specifically trained LMs. Min *et al.*<sup>[[59,](#page-17-14) [69](#page-18-2)]</sup> trained an LM model for decomposing the original task into sub-tasks. Nye *et al.*[[88\]](#page-19-13) trained the LLM to produce intermediate steps stored in a scratch pad for later usage. Zelikman *et al.*[[89\]](#page-19-14) utilized the intermediate outputs that lead to the correct answer as the target to fine-tune the LLM. Wang *et al.*[[87\]](#page-19-2) proposed an iterative prompting framework using a context-aware prompter. The prompter consists of a set of soft prompts that are prepared for the encoder [an](#page-19-3)d decoder of the LLMs, respectively. Taylor *et al.*<sup>[\[90](#page-19-3)]</sup> employed step-by-step solutions of scientific papers in the training corpus, which enables the LM to output reasoning steps if required.

## 5.3 Trends for Multiple Prompting Methods

Ensemble-based methods are easy to implement and flexible to incorporate with various strategies, e.g. expanding the input space and aggregating the output space. However, this brings limited advantages for complex problems whose final answers are hard to obtain directly, but rely heavily on the intermediate thinking steps. Therefore, multi-turn PE methods emerged. A multi-turn method essentially adjusts its input dynamically during the interaction based on the knowledge and feedback from the LLM or external tools. In this way, LLMs can leverage more context and understand better the true intention of the user. Initially, specialized LLMs are trained to handle planning and solving specific subtasks, which not only introduces extra training effort but also constrains the generalization capability of LLM. With the increasing understanding ability and larger input length of LLMs, in-context learning becomes the preferred

paradigm, which utilizes embedded knowledge and the capability of LLMs to handle various tasks via prompting. This paradigm soon dominated because of its efficiency and flexibility.

There are two trends in multiple prompting engineering.

• Developing an enhanced adaptive prompting strategy for LLM-based task decomposition is imperative. The extensive range and intricacy of tasks render human-based or rule-based task decomposition infeasible. While some studies have explored the use of LLM prompting to generate intermediate questions or actions for specific tasks, a comprehensive strategy is currently lacking.

• Enabling LLMs to leverage tools without the need for fine-tuning is a crucial objective. By incorporating external tools, LLMs can address their limitations in specialized domains or capabilities. Previous studies<sup>[[85\]](#page-18-10)</sup> have employed fine-tuning based approaches to train LLMs in utilizing web search or other tools accessible through APIs.

From the communication theory perspective, multiple prompting methods evolved from the extension in the spatial domain (ensemble-based methods) into the temporal domain (mulit-turn), to better align the user's intention and LLM's capability by decomposing the user's request and leveraging external tools.

## <span id="page-13-0"></span>6 Discussion

Researchers have proposed several surveys to recapitulate [t](#page-15-6)[he](#page-19-15) [rap](#page-20-0)id advancements in the field of PE methods[\[7,](#page-15-6) [103](#page-19-15)–[107](#page-20-0)] . To name a few, Liu *et. al* proposed a comprehensive survey about existing PE methods, which covers common aspects like template engineering, answering enginee[ri](#page-15-6)ng, training strategies, appli-cations, and challenges<sup>[[7](#page-15-6)]</sup>. They revealed the development history of prompting learning and describe a set of mathematical notations that could summarize most of the existing studies. Furthermore, they considered prompt-based learning as a new paradigm that revolves [ar](#page-19-15)ound the way we look at NLP. In another survey<sup>[[103](#page-19-15)]</sup> that mainly focuses on the reasoning abilities (e.g., arithmetic, commonsense, symbolic reasoning, logical, and multi-modal) of LLMs, Qiao *et al.* summarized the studies that harness these reasoning abilities via advanced PE methods like chain-ofthough and generated knowledge prompts. Additionally, some focused surveys cover specific topics like parameter-efficient fine-tuning (PEFT) LLMs using PE methods<sup>[\[104\]](#page-19-16)</sup>. Different from the above-mentioned studies, we try to interpret existing PE methods from a communication theory perspective.

Following this line of research, we also would like to discuss some potential challenges and future directions for PE methods, which could be divided into three categories including finding the optimal prompts, privacy issue and concern, and interactive and multi-turn prompting.

• *Finding the Optimal Prompts*. One of the points of discrete prompts is that it is difficult to design and choose an optimal prompt, causing its instability. Although soft prompts partly address this problem, the discrete prompt is still very important because it has good interpretability and has been proven to be able to help soft prompts search effectively. Looking through the existing methods, we can find that accuracy-based criteria are resource-consuming, while LMbased log probability is not sufficient to evaluate the prompt. Therefore, a well-designed ranking criterion combined with a mass of auto-based generated prompts may be a good direction for the future. Furthermore, even though the prompt has been proven effective in many tasks such as classification and text generation, most of the existing work has to design a specific prompt for a given task, which makes it com-plex and complicated<sup>[\[108\]](#page-20-1)</sup>. Thus, how to generate a task-agnostic prompt or transfer the prompt to other fields quickly may be a challenging problem. Discrete  $(meta-learning<sup>[109]</sup>)$  $(meta-learning<sup>[109]</sup>)$  $(meta-learning<sup>[109]</sup>)$  and continuous (decompositi- $\text{on}^{[110]}$  $\text{on}^{[110]}$  $\text{on}^{[110]}$  prompts are applied to tackle this issue. However, they are not well-optimized and can not serve unseen tasks.

• *Privacy Issue and Concern*. There are two aspects of privacy and security issue in LLMs. First, users' data may be leaked during the training and inference of LLMs. For instance, training LLMs requires vast amounts of data including personal information, private conversations, or copyrighted material. By providing a series of queries or prompts, an attacker might be able to extract personal details or confidential information from the model's responses. Privacy-preserving methods including techniques such as differential privacy, homomorphic encryption, and federated learning<sup>[[111](#page-20-4)–[113](#page-20-5)]</sup> may preserve the privacy of the data used for training and inference. Second, the LLMs may be stolen by attackers to misuse. LLMs are highly valuable assets, requiring substantial time and financial investment for their training. Protecting them from unauthorized access and misuse is crucial. Developing robust security measures, such as watermarking techniques<sup>[[114\]](#page-20-6)</sup>, is essential to prevent theft and ensure the rightful ownership of LLMs.

• *Interactive and Multi-Turn Prompting*. Besides the automation in prompting methods, humans in the loop can bring more controllability, transparency, and explainability over the process, producing more reliable results. The success of the chain-of-thoughts methodology $[115]$  demonstrates the "thinking path" can enhance LLMs' reasoning capability. This property can also be exploited to generate step-by-step tasksolving procedures like scratch paper in exams, so that the final answer can be better justified. Following this idea, Wu *et al.*[\[76](#page-18-18)] built an interactive framework involving human interaction for better controllability of the process. However, frequent human intervention will diminish the efficiency gained by using LLMs. Therefore, in addition to the granularity of decomposed tasks, it is also required to determine when to involve human feedback. This could be designed manually for each task, but it would be much more efficient if LLMs could plan these stages by themselves.

• *Bias and Fairness*. LLMs often tend to internalize biases presented in their training datasets, making the mitigation of such biases and the pursuit of fairness a key aspe[ct o](#page-20-8)f existing PE methods. For example, Zhao *et al.*<sup>[\[116\]](#page-20-8)</sup> revealed that factors such as the structure of prompts, demonstrations contained in the prompt, and even the order of these demonstrations can lead to diverse performance in in-context learning prompts, and they further p[rop](#page-20-9)osed calibration to alleviate the bias. Schick *et al.*[[117](#page-20-9)] designed biased or debiased instructions to guide the LLMs to conduct self-diagnosis and self-debiasing. Furthermore, the social biases exhibited by LLMs can potentially lead to discriminatory actions or content targeted at specific groups or demographics. Such problems are often caused from stereotypes that perpetuate harmful generalizations related [to](#page-20-10) gender, race, and religion. For instance, Liu *et al.*<sup>[\[118\]](#page-20-10)</sup> introduced a novel prompting approach that reveals how existing LLMs exhibit social biases during text-to-SQL prediction tasks. Despite this progress, the challenge of mitigating biases in LLMs using PE methods remains an area that requires further investigation.

## <span id="page-14-0"></span>7 Conclusions

This article summarizes the prompting methods from a perspective of communication theory which

provides a coherent explanation of different prompt engineering (PE) methods in terms of their objectives and underlying principles. Theoretical analysis reveals that the ultimate goal of PE is to reduce the information misunderstanding between the users and the LLMs. This novel view facilities a unified review of three PE methods and offers and insights into scenarios where existing prompting methods come short. We hope this survey will inspire researchers with a new understanding of the related issues in prompting methods, therefore stimulating progress in this promising area.

Conflict of Interest The authors declare that they have no conflict of interest.

Yuan-Feng Song is a researcher in WeBank AI Group, WeBank, Shenzhen. His research interests include learning to rank, data visualization, and speech-driven applications. In his career, he has published several papers in venues such as KDD, ICDM,

EMNLP, MM, TIST, TKDE, and SIGMOD.

Yuan-Qin He is currently a researcher with WeBank AI Group, We-Bank, Shenzhen. He received his B.S. degree in Physics from Shanghai Jiao Tong University, and his Ph.D. degree in physics from the Technical University of Munich, Munich, in

2017. His research interests include machine learning and federated learning.

Xue-Fang Zhao received her Master degree in computer science from the Tsinghua University, Beijing, in 2020. She is currently a research engineer at WeBank AI Group, WeBank, Shenzhen. Her research interests include natural language processing and

speech recognition.

Han-Lin Gu received his B.S. degree in mathematics from University of Science and Technology of China, Hefei, in 2017. He received his Ph.D. degree in mathematics from Hong Kong University of Science and Technology, Hong Kong, in 2022. He now

works as a senior researcher at WeBank AI Group, We-Bank, Shenzhen. His research interests include federated learning and privacy-preserving methodology. He has published a series of papers in TPAMI, TDSC, IJCAI, PAKDD, and so on.

Di Jiang received his Ph.D. degree in computer science from the Hong Kong University of Science and Technology, Hong Kong, in 2014. He is currently the principal scientist at We-Bank AI Group, WeBank, Shenzhen. His research interests include informa-

tion retrieval, natural language processing, and massive data management.

Hai-Jun Yang received his B.E. degree in 2008 and his M.S. degree in 2011, both from Harbin Institute of Technology, Harbin. He is currently the Senior Manager of the AI Group at WeBank, Shenzhen, mainly responsible for promoting the integration and

implementation of AI technology with WeBank in customer service, risk control, marketing, and other business scenarios.

Li-Xin Fan is the Principal Scientist of Artificial Intelligence at We-Bank, Shenzhen, and the Chairman of the Federal Learning Industry Ecological Development Alliance. His research fields include machine learning and deep learning, computer vision

and pattern recognition, image and video processing, 3D big data processing, data visualization and rendering, augmented and virtual reality, mobile computing and ubiquitous computing, and intelligent man-machine interface. He is the author of more than 70 international journals and conference articles. He has worked at Nokia Research Center and Xerox Research Center Europe. His research includes the well-known Bag of Keypoints image classification method. He has participated in NIPS/ NeurIPS, ICML, CVPR, ICCV, ECCV, IJCAI and other top artificial intelligence conferences for a long time, served as area chair of AAAI, and organized workshops in various technical fields. He is also the inventor of more than one hundred patents filed in the United States, Europe, and China, and the chairman of the IEEE P2894 Explainable Artificial Intelligence (XAI) Standard Working Group.
